Adaptive Estimation In Weighted Group

Adaptive estimation in weighted group testing Abstract: We consider a generalization of the problem of estimating the support size of a hidden subset S of a universe U from samples. This framework falls under the group testing [1] and the conditional sampling models [2, 3].

estimation scenario does therefore fall under our weighted group testing model, and can benefit from the techniques we develop. Organization: In Section II, we formally define the setting of “weighted group testing” that we shall work in. In Section V, we describe and analyze an (adaptive) algorithm for this generalization of group testing.

We further study two versions of weighted group lasso—adaptive group lasso and integrative group lasso. Adaptive group lasso is a two-stage procedure. In the first stage, we obtain a n -consistent estimator $\hat{\Theta}^0$, for example, the least square estimator $\hat{\Theta}^L$. Then we plug $\hat{\Theta}^p$ into the weight function $w(z)$ for $p = 1, \dots, P$. The objective function of the adaptive group lasso is $(1) \arg \min_{\Theta} \{SSE(\Theta) + \lambda (\sum_{p=1}^P w(\hat{\Theta}^p) \|\Theta\|_1)\}$.

The weighted mean information entropy is adopted as the basis for partitioning of BCS which results in a flexible block group. Furthermore, the synthetic feature (SF) based on local saliency and variance is introduced to step-less adaptive sampling that works well in distinguishing and sampling between smooth blocks and detail blocks.

4.2. Unblinded SSR Versus Group Sequential Designs. To provide considerations for choosing between ubSSR and GSD in a simplified setting where one of the two possible sample sizes, N_1 and N_2 , are considered for the trial. The sample size N_1 is deemed sufficient to address key questions of interest in the trial and is expected to provide adequate power if an optimistic treatment effect is ...

Adaptive design methods in clinical trials - a review

In group sequential designs and other adaptive designs, access to the interim data gives the ability to answer the important question of how likely a trial is to succeed based on the information accrued so far. The two most commonly cited statistics to evaluate this is conditional power and predictive power.

An improved spectral reflectance estimation method is developed to transform raw camera RGB responses to spectral reflectance.
