Precast Segmental Box Girder Bridge

Segmental box girder bridges externally post-tensioned are one of the major new developments in bridge engineering in the last years. In contrast to 'classical' monolithic constructions a segmental bridge consists of „small“ precast elements stressed together by external tendons (fig. 1). The many advantages of this type of

A segmental bridge is a bridge built in short sections, i.e., one piece at a time, as opposed to traditional methods that build a bridge in very large sections. The bridge is made of concrete that is either cast-in-place or precast concrete. These bridges are very economical for long spans, especially when access to the construction site is restricted. They are also chosen for their aesthetic appeal.

It is noted that when constructing a large number of prestressed concrete bridges, precasting has a number of advantages over cast-in-place construction. A box girder is considered a better structural shape for long spans than an I-section girder. The box girder is very compact.

DESIGN OF SEGMENTAL BRIDGES

Precast struts and transverse trusses are sometimes combined in cable-stayed bridges with one central plane of stay cables supporting twin precast segmental box girders, while they are rarely necessary with twin box girders supported at the edges with two planes of stay cables. Precast segmental technology, however, is rarely applied to modern cable-stayed bridges designed for long service life because of the weight of these structures and the huge number of longitudinal and transverse ...

Span-by-Span Construction of Precast Segmental Bridges ...

Segmental bridge construction (Second Stage Expressway in Bangkok) [1], [13]. Adjacent segments must match perfectly to guarantee the load transfer (shear and normal forces) through the un-reinforced dry joint between two precast elements. Thus match casting must be used as a segments production technique.

When the precast segments are too heavy for ground transportation, these bridges are cast in-place with form travelers. Two tension diagonals connect the cable anchor points to the bottom web-slab nodes of the box girder to provide direct vertical support to the webs.

Twin Box Girders for Precast Segmental Cable-Stayed Bridges?

Precast girder formwork has advantages of high-precision, simple structure, retractile, easy-demoulding and simple operation. It can be hoisted or dragged to casting site integrally, and demoulded integrally or piecemeal after concrete achieving the strength, then pull out the inner mould from the girder.

Being the first precast segmental bridge built using short-line match-casting method in China, the approach structure consisted of 52 spans of single cell box girders. The typical bridge units were formed by 5-span or 10-span continuous deck supported on the pot bearings (Figure 2).

Typical span lengths for segmental bridges are as follows: (i) cast-in-place posttensioned box girder of constant depth, 30–90 m; (ii) precast posttensioned box girder of constant depth erected using balanced cantilever, 30–90 m; (iii) variable depth precast balanced cantilever segmental, 60–180 m; and (iv) cast-in-place cantilever, 60–300 m.

Segmental Bridge - an overview | ScienceDirect Topics

ABSTRACT: Precast concrete segmental bridges (PCSBs) have been the most common design technology used in the last decades. It is widely recognized that segmental bridges have better durability, lower life-cycle costs and higher quality for maintenance than other types of bridges. PCSBs with externally prestressed tendons have become very popular in
